(Dated: August 17, 2012)

We have recently proposed a novel self tuning mechanism to alleviate the famous cosmological constant problem, based on the general scalar tensor theory proposed by Horndeski. The self-tuning model ends up consisting of four geometric terms in the action, with each term containing a free potential function of the scalar field; the four together being labeled as the *Fab-Four*. In this paper we begin the important task of deriving the cosmology associated with the *Fab-Four* Lagrangian. Performing a phase plane analysis of the system we are able to obtain a number of fixed points for the system, with some remarkable new solutions emerging from the trade-off between the various potentials. As well as obtaining inflationary solutions we also find conventional radiation/matter-like solutions, but in regimes where the energy density is dominated by a cosmological constant, and where we do not have any explicit forms of radiation or matter. Stability conditions for matter solutions are obtained and we show how it is possible for there to exist an extended period of 'matter domination' opening up the possibility that we can generate cosmological structures, and recover a consistent cosmology even in the presence of a large cosmological constant.

I. INTRODUCTION

Over the last decade or so, as we have struggled to explain the nature of dark energy that is believed to be responsible for the observed acceleration of the Universe, interest has turned to the possibility that rather than being caused by an unknown form of energy density, the acceleration could be a result of a modification of Einstein's theory of General Relativity. It has resulted in an explosion of papers in the field, see [4] for a detailed review of the various approaches that have been adopted; one particularly interesting direction involves scalar-tensor combinations. It seems sensible to require that any theory maintains second order field equations, and the most general scalar-tensor theory satisfying that criteria was written down back in 1974 by Horndeski [3] (it has recently been rediscovered in [5]). Such theories of modified gravity cover a wide range of models, ranging from Brans-Dicke gravity [6] to the recent models [7, 8] inspired by galileon theory [9]; the latter being examples of higher order scalar tensor Lagrangians with second order field equations. Of course all of these models can be considered as special cases of Horndeski's original action. Once the action was rediscovered, it did not take long before a perturbative analysis of the background evolution equations was carried out [10, 11], which allows for a stability analysis to be performed on the various background solutions.

In [2] we obtained a new class of models arising out of Horndeski's theory on FLRW backgrounds. The new models gave a viable self-tuning mechanism for solving the (old) cosmological constant problem, at least at the classical level, by completely screening the spacetime curvature from the net cosmological constant. In order to evade the famous no-go theorem of Weinberg [12], the new solutions did not assume Poincaré invariance to hold at the level of the solution (as Weinberg assumed), rather we allowed it to be broken in the scalar field sector. This is similar to a route adopted in [13] where the scalar field is allowed to break Poincaré invariance on the self-tuning vacua, whilst maintaining a flat spacetime geometry. In [2] we provided a brief sketch of how the system works, showing that by demanding the self-tuning mechanism continues to work through phase transitions, so causing the vacuum energy to jump, we get powerful restrictions on the allowed form of Horndeski's original theory. Whereas the original model is complicated, with many arbitrary functions of both the scalar and its derivatives, we showed that by assuming matter is only minimally coupled to the metric (required to satisfy equivalence principle (EP) considerations) then once the model is passed through our self-tuning filter, it reduces in form to just four base Lagrangians each depending on an arbitrary function of the scalar only, coupled to a curvature term. We called these base Lagrangians the *Fab-Four*: $\mathcal{L}_j$, $\mathcal{L}_p$, $\mathcal{L}_g$, $\mathcal{L}_r$, where the indices refer to *John, Paul, George* and *Ringo*. This was followed up in [14] with a detailed derivation of the conditions that lead to the four base Lagrangians just mentioned, in which we showed how they naturally lead to self-tuning solutions. Moreover in [14] we began to address the important question of the stability of the classical solutions to quantum corrections and demonstrated that at least

heuristically the self-tuning solutions can be guaranteed to receive only small quantum corrections thereby not spoiling the self-tuning nature of the solutions.

The purpose of this paper is to begin the discussion of the cosmology associated with the *Fab-Four* Lagrangian. Without a sensible cosmology the model is nothing other than an interesting aside that may give some feeling as to how the cosmological constant can be addressed, but in itself does not have anything to say about our Universe. This is a non-trivial exercise. Note that some aspects of *Fab-Four* cosmology were touched upon in [15].

Recall from [2] that we are dealing with situations where the net cosmological constant may be large compared to any other energy density in the system. In the conventional cosmological scenario this would inevitably lead to a period of rapid acceleration, with no prospect of a radiation or matter dominated period, hence no chance for nucleosynthesis to take place or structures to form in our Universe. We will require the four potential functions in the *Fab-Four* action to act together and conspire to alleviate the influence of a net large cosmological constant before the final self tuning solution is reached. After all, we do not live in that solution just yet. To attack the problem, we will rewrite the equations of motion for the scalar field and the Friedmann equation in terms of a dynamical system allowing us to look for late time attractor solutions and to determine the stability of those solutions.

The initial conclusions are positive, we are able to find combinations of the four potentials that do indeed lead to inflation/radiation/matter dominated like periods, with the latter two entering the self-tuning regime at very late times. For matter domination like behaviour, we explicitly show that there are large regions of parameter space for which the corresponding solutions are perturbatively stable. These solutions are remarkable. Because we are interested in the case where the cosmological constant dominates the source, we have focussed on the case where no additional sources are present. Thus, we are able to find perturbatively stable matter-like solutions that are driven by a cosmological constant. What is happening is that the scalar field is working to screen the pressure component of the cosmological constant before its energy density. Eventually it will also screen the energy density, but the potentials allow for an intermediate period in which Λ essentially behaves like cold dark matter. This is the main result of this paper.

The layout is as follows: in section II we briefly recap the key Hamiltonian and scalar field equations of motion for the *Fab-Four* system arising from the original action of Horndeski [3] that is minimally coupled to matter. We do not rederive them, rather direct the reader to [14] for a rigorous derivation of the Lagrangian and evolution equations. We begin exploring the cosmology of this self-tuning scenario in section III, focussing on how each member of the *Fab-Four* behaves in isolation. To see how the various members behave in combination we rewrite the field equations as first order equations using a dynamical systems approach in section IV. We switch off curvature in order to focus on the cosmological epoch prior to self-tuning, and find scaling solutions corresponding to different types of cosmology such as radiation domination, matter domination and inflation. Strictly speaking, some of these matter-like solutions are only fixed points for vanishing cosmological constant. Even so, as we show in section V, both analytically and through numerical simulations, they still provide an excellent approximation to the true cosmology even when there is a large non-vanishing cosmological constant.

The reader not overly concerned with the details of how we arrived at interesting classes of *Fab-Four* potentials should probably skip section IV and proceed directly to section V. Here we summarize the main findings of section IV, as well as providing numerical simulations of solutions when spatial curvature is turned on. For the matter-like solutions, we also consider cosmological perturbations to weed out any problems with ghost and/or gradient instabilities. Whilst some solutions are unstable, others are perfectly well behaved. We conclude in section VI.

II. THE SELF TUNING LAGRANGIAN – THE *FAB-FOUR*

Given that we are interested in the cosmology associated with the *Fab-Four*, we will consider homogeneous and isotropic spatial geometries of the form,

$$ds^2 = -dt^2 + a^2(t)\left[\frac{dr^2}{1-kr^2} + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)\right], \tag{1}$$

with k the constant denoting the spatial curvature. In [2, 14] we derived the sector of Horndeski's theory [3] that exhibits self-tuning. What does that mean? Given our cosmological background in vacuum (1), and the expectation that the matter sector can contribute a constant vacuum energy density, we identify with the net cosmological constant, $\rho_\Lambda = \rho_\Lambda^{bare} + \langle\rho_m\rangle_{\rm vac}$. In a self tuning scenario the net cosmological constant should not have an impact on the spacetime curvature, so whatever the value of ρ_Λ, we still want to have a portion of flat spacetime[1]. What makes it applicable to cosmology is that this argument should hold when the matter sector goes through a phase-transition, changing the overall value of ρ_Λ by a constant amount, for example GUT phase transitions, EWK phase transitions etc. For this to work, any abrupt change in the matter sector has to be completely absorbed by the scalar field leaving the geometry unchanged. Hence the scalar field tunes itself to each change in ρ_Λ and this has to be allowed independently of the time (or epoque) of transition. The self tuning solution is Ricci flat, which tells us that at self tuning we have

$$H^2 \;=\; -\frac{k}{a^2}. \tag{2}$$

For $k = 0$ we have a flat slicing of Minkowski, whilst for $k < 0$ we have a Milne slicing. For $k > 0$ no flat spacetime slicing is possible. With this demand of a viable self-tuning mechanism we were able to place powerful restrictions on the allowed form of Horndeski's original Lagrangian [14]. Whereas the original model is complicated, with many arbitrary functions of both the scalar and its derivatives, we showed that a self-tuning solution dramatically restricted the Lagrangian in form to just four base Lagrangians each depending on an arbitrary function of the scalar only, coupled to a curvature term. We called these base Lagrangians the *Fab-Four*, given by the following

$$\mathcal{L}_j \;=\; \sqrt{-g}V_j(\phi)G^{\mu\nu}\nabla_\mu\phi\nabla_\nu\phi, \tag{3}$$
$$\mathcal{L}_p \;=\; \sqrt{-g}V_p(\phi)P^{\mu\nu\alpha\beta}\nabla_\mu\phi\nabla_\alpha\phi\nabla_\nu\nabla_\beta\phi, \tag{4}$$
$$\mathcal{L}_g \;=\; \sqrt{-g}V_g(\phi)R, \tag{5}$$
$$\mathcal{L}_r \;=\; \sqrt{-g}V_r(\phi)\hat{\mathcal{G}}, \tag{6}$$

where R is the Ricci scalar, $G_{\mu\nu}$ is the Einstein tensor, $P_{\mu\nu\alpha\beta}$ is the double dual of the Riemann tensor [1], and $\hat{\mathcal{G}} = R^{\mu\nu\alpha\beta}R_{\mu\nu\alpha\beta} - 4R^{\mu\nu}R_{\mu\nu} + R^2$ is the Gauss-Bonnet combination. Provided that $\{V_j, V_p, V_g\} \neq \{0, 0, constant\}$ then these Lagrangian's naturally lead to the self-tuning solutions. Intriguingly, it follows that this constraint means that General Relativity is *not* a *Fab-Four* theory, which in itself is consistent with the fact that it does not have self-tuning solutions. By "self-tuning", we mean that

- the theory should admit a Minkowski vacuum for any value of the net cosmological constant
- this should remain true before and after any phase transition where the cosmological constant jumps instantaneously by a finite amount.
- the theory should permit a non-trivial cosmology

Of course, this last condition ensures that Minkowski space is not the only cosmological solution available, which is important because we know from observation that the universe had to leave Minkowski space during its evolution. Fortunately this last condition is still allowed because the cosmological field equations are dynamical, with the Minkowski solution corresponding to a late time fixed point, meaning that once we are on a Minkowski solution, we stay there – otherwise we evolve to it dynamically. Note that for a homogeneous scalar, self-tuning is only possible for a Milne slicing of Minkowski. Indeed, the rate at which self-tuning kicks in and the solutions evolve towards the Milne Universe is controlled by magnitude of the spatial curvature, $|k|$. This will be evident from the numerical plots shown in section V.

---

[1] Given the value of the tiny observed cosmological constant, for our purposes, flat spacetime is a very good approximation.

We begin our analysis of the cosmology by writing down the Hamiltonian density and scalar field equations of motion arising from the *Fab-Four* Lagrangian. Using the line element (1) the Lagrangians (3) - (6) become

$$\mathcal{L}_j = 3a^3V_j(\phi)\dot{\phi}^2(H^2+k/a^2), \tag{7}$$
$$\mathcal{L}_p = -3a^3V_p(\phi)\dot{\phi}^3H(H^2+k/a^2), \tag{8}$$
$$\mathcal{L}_g = -6a^3V_g(\phi)(H^2-k/a^2) - 6a^3V_{g,\phi}(\phi)H\dot{\phi}, \tag{9}$$
$$\mathcal{L}_r = -8a^3V_{r,\phi}(\phi)\dot{\phi}H(H^2+3k/a^2), \tag{10}$$

where "dot" corresponds to differentiation with respect to t, $H=\frac{\dot{a}}{a}$ is the Hubble parameter, and $V_{r,\phi}(\phi)\equiv\frac{dV_r(\phi)}{d\phi}$ etc. Using $E_j^{(\phi)}=-\frac{d}{dt}\left(\frac{\partial\mathcal{L}_j}{\partial\dot{\phi}}\right)+\frac{\partial\mathcal{L}_j}{\partial\phi}$, $\mathcal{H}_j=\left(\frac{\partial\mathcal{L}_j}{\partial\dot{\phi}}\right)\dot{\phi}+\left(\frac{\partial\mathcal{L}_j}{\partial\dot{a}}\right)\dot{a}-\mathcal{L}_j$ etc, we find that the Hamiltonian density in the presence of a matter source ρ_m is

$$\mathcal{H}=\mathcal{H}_j+\mathcal{H}_p+\mathcal{H}_g+\mathcal{H}_r+\rho_\Lambda^{bare}=-\rho_m, \tag{11}$$

where

$$\mathcal{H}_j = 3V_j(\phi)\dot{\phi}^2\left(3H^2+\frac{k}{a^2}\right), \tag{12}$$
$$\mathcal{H}_p = -3V_p(\phi)\dot{\phi}^3H\left(5H^2+3\frac{k}{a^2}\right), \tag{13}$$
$$\mathcal{H}_g = -6V_g(\phi)\left[\left(H^2+\frac{k}{a^2}\right)+H\dot{\phi}\frac{V_{g,\phi}(\phi)}{V_g(\phi)}\right], \tag{14}$$
$$\mathcal{H}_r = -24V_{r,\phi}(\phi)\dot{\phi}H\left(H^2+\frac{k}{a^2}\right). \tag{15}$$

The scalar equation of motion is given by

$$E^{(\phi)}=E_j^{(\phi)}+E_p^{(\phi)}+E_g^{(\phi)}+E_r^{(\phi)}=0, \tag{16}$$

where

$$E_j^{(\phi)} = 6\frac{d}{dt}\left[a^3V_j(\phi)\dot{\phi}\Delta_2\right]-3a^3V_{j,\phi}(\phi)\dot{\phi}^2\Delta_2, \tag{17}$$
$$E_p^{(\phi)} = -9\frac{d}{dt}\left[a^3V_p(\phi)\dot{\phi}^2H\Delta_2\right]+3a^3V_{p,\phi}(\phi)\dot{\phi}^3H\Delta_2, \tag{18}$$
$$E_g^{(\phi)} = -6\frac{d}{dt}\left[a^3V_{g,\phi}(\phi)\Delta_1\right]+6a^3V_{g,\phi\phi}(\phi)\dot{\phi}\Delta_1,+6a^3V_{g,\phi}(\phi)\Delta_1^2 \tag{19}$$
$$E_r^{(\phi)} = -24V_{r,\phi}(\phi)\frac{d}{dt}\left[a^3\left(\frac{k}{a^2}\Delta_1+\frac{1}{3}\Delta_3\right)\right], \tag{20}$$

and we have defined the quantity

$$\Delta_n = H^n-\left(\frac{\sqrt{-k}}{a}\right)^n, \tag{21}$$

which vanishes when we are on the self-tuning solution. As a result, it is easy to see that $E^{(\phi)}$ also vanishes automatically during self-tuning. However, we note that the condition for self-tuning requires that the full scalar equation of motion should *not be independent* of $\ddot{a}$, and this is important as it ensures that the self-tuning solution can be evolved to dynamically, thereby allowing for a non-trivial cosmology.

What is it we would like to recover from these equations? Ideally we want to find a cosmology consistent with observations, that does not rely on any particular value for the cosmological constant. It should be able to accommodate an early period of inflation driven by some combination of the four potentials, followed by

an extended period of radiation and matter domination during which nucleosynthesis could take place and in which structures could form. This would be followed by a late period of cosmic acceleration corresponding to the dark energy domination in which we find ourselves today. This is obviously a tall order, but as we will see, something that is not beyond the *Fab-Four*. In the next section, we will briefly examine the cosmological behaviour of each member of the *Fab-Four* in isolation to gain some intuition as to how each term will drive cosmology. This will be followed by a much more thorough analysis in section IV: we introduce the powerful formalism of dynamical systems to rewrite the dynamics as a set of first order differential equations that we can then solve for their fixed points, allowing us to obtain a new set of cosmological solutions.

III. THE COSMOLOGY OF EACH MEMBER OF THE *FAB-FOUR*

To get a feel for how each member of the *Fab-Four* drives cosmology, we will briefly consider how they each behave in isolation, in the presence of a net cosmological, but no additional matter excitations. We neglect the latter because we are ultimately interested in the case where the net cosmological constant dominates the source completely, so any matter exciation will be subleading. As a result, we set $\rho_m = \langle\rho_m\rangle_{\rm vac}$ in (11) and define the net cosomological constant $\rho_\Lambda = \rho_\Lambda^{bare} + \langle\rho_m\rangle_{\rm vac}$.

It is convenient to rewrite the equations of motion (11) and (16) using $N = \ln a$ as our evolution parameter, as opposed to proper time. Using $\dot\phi = H\phi'$ and $a' = a$, (where $\phi' \equiv d\phi/dN$ etc...), we find that

$$\mathcal{H}_j + \mathcal{H}_p + \mathcal{H}_g + \mathcal{H}_r = -\rho_\Lambda, \tag{22}$$

$$E_j^{(\phi)} + E_p^{(\phi)} + E_g^{(\phi)} + E_r^{(\phi)} = 0, \tag{23}$$

where

$$\mathcal{H}_j = 3V_j(\phi)\phi'^2H^2\left(3H^2 + \frac{k}{a^2}\right), \tag{24}$$

$$\mathcal{H}_p = -3V_p(\phi)\phi'^3H^4\left(5H^2 + 3\frac{k}{a^2}\right), \tag{25}$$

$$\mathcal{H}_g = -6V_g(\phi)\left[\left(H^2 + \frac{k}{a^2}\right) + H^2\frac{V_{g,\phi}(\phi)\phi'}{V_g(\phi)}\right], \tag{26}$$

$$\mathcal{H}_r = -24V_{r,\phi}(\phi)\phi'H^2\left(H^2 + \frac{k}{a^2}\right), \tag{27}$$

and

$$E_j^{(\phi)}\dot\phi/H = \frac{1}{a^3\Delta_2}\left[\frac{\mathcal{H}_j a^6\Delta_2^2}{3\Delta_2 - 2\frac{k}{a^2}}\right]' \tag{28}$$

$$E_p^{(\phi)}\dot\phi/H = \frac{2}{a^{3/2}(H\Delta_2)^{1/2}}\left[\frac{\mathcal{H}_p a^{9/2}(H\Delta_2)^{1/2}\Delta_2}{5\Delta_2 - 2\frac{k}{a^2}}\right]' \tag{29}$$

$$E_g^{(\phi)}\dot\phi/H = -3\frac{V_g'}{a}(\Delta_2 a^4)' \tag{30}$$

$$E_r^{(\phi)}\dot\phi/H = \frac{\mathcal{H}_r}{H\Delta_2}\left[a^3\left(\frac{k}{a^2}\Delta_1 + \frac{1}{3}\Delta_3\right)\right]'. \tag{31}$$

Now, we are interested in the case where only one member of the *Fab-Four* is switched on. We therefore take $\mathcal{H}_i = -\rho_\Lambda =$ constant, and solve $E_i^{(\phi)} = 0$ for $i = j, p, g, r$. We know that at late times the solutions asymptote to a curvature dominated Milne universe $H^2 \to -\frac{k}{a^2}$ by the self-tuning mechanism [2, 14]. To examine what happens before that we consider the opposite regime in which the curvature is subdominant;

the results are listed below:

$$V_j \text{ only}: \qquad H^2 = \frac{M^2}{a^6}(1+\mathcal{O}(k/a^2)) \qquad \text{“stiff fluid”} \tag{32}$$

$$V_p \text{ only}: \qquad H^2 = \frac{M^2}{a^6}(1+\mathcal{O}(k/a^2)) \qquad \text{“stiff fluid’} \tag{33}$$

$$V_g \text{ only}: \qquad H^2 = \frac{M^2}{a^4} - \frac{k}{a^2} \qquad \text{“radiation”} \tag{34}$$

$$V_r \text{ only}: \qquad H^2 = \frac{M^2}{a^2}(1+\mathcal{O}(k/a^2)) \qquad \text{“curvature”} \tag{35}$$

where M is some mass scale that arises as a constant on integration in each case. V_j and V_p both behave like a stiff fluid with equation of state $w = 1$, which might have been expected since the corresponding Lagrangians contain derivative terms for ϕ, and we get a kinetically driven scalar field. In contrast, V_g behaves like radiation whilst V_r behaves like curvature. It is worth emphasizing that in each case the source is a cosmological constant with equation of state $w = -1$, and yet the resulting cosmology behaves nothing like an inflationary de Sitter solution. The scalar field screens the pressure components of the source in a number of different ways, depending on which member of the *Fab-Four* is turned on. This allows us to be optimistic about extracting realistic cosmological solutions from the interplay between terms in the full *Fab-Four* theory. In the next section, we will show using a detailed dynamical systems analysis, that this is indeed the case

IV. A DYNAMICAL SYSTEMS APPROACH TO THE *FAB-FOUR* COSMOLOGY

Our system of equations (11) and (16) are complicated second order equations and generally will not present tractable solutions. A powerful method to obtain attractor solutions is to adopt a phase plane analysis through a dynamical systems approach that allows us to both reduce the order of the differential equations but to also obtain the fixed point solutions without having to obtain the full dynamics of the system (see for example [16, 17]). This is a particularly powerful technique when we know what sort of fixed point solutions we are aiming for, in our case they correspond to radiation or matter domination or inflationary expansions. The reader who is simply interested in the cosmological solutions rather than their derivation may want to skip this section, and proceed directly to section V.

We continue with $N = \ln a$ as the “time” variable, and note that we will regularly come across the following combinations

$$h = \frac{H'}{H}, \qquad \sigma = \frac{\sqrt{-k}}{Ha}, \tag{36}$$

from which it follows that when $h = const$ we have

$$H = H_0 a^h \tag{37}$$

$$a = a_0(t-t_\star)^{-1/h}, \tag{38}$$

with H_0, a_0 and $t_\star$ as constants of integration; these will be used when we examine the fixed-points. If we were to neglect the spatial curvature then matter-like expansion would correspond to $h = -3/2$ and radiation-like expansion to $h = -2$. Curvature domination corresponds to $h = -1$ and an inflationary trajectory would correspond to the region $-1 < h < 0$, with the solution approaching de Sitter expansion as $h \to 0$. We will not consider the case where we have exactly $h = 0$, as it will correspond to a singular limit of our system.

Another useful quantity when trying to understand particular solutions is the deceleration parameter that is given by

$$q = -\frac{a\ddot{a}}{\dot{a}^2}. \tag{39}$$

So for $a \sim t^p \sim t^{-1/h}$ we get

$$q \;=\; -\frac{p(p-1)}{p^2} = -(h+1). \tag{40}$$

The system of equations corresponding to (11) and (16) are quite complicated and so we require a few new variables to fully establish the dynamical system. We do this by introducing

$$x = H^\alpha \phi', \tag{41}$$

and

$$y_j = H^{\beta_j} V_j, \qquad y_p = H^{\beta_p} V_p, \qquad y_g = H^{\beta_g} V_g, \qquad y_r = H^{\beta_r} V_{r,\phi}, \tag{42}$$

$$\lambda_j = H^{\gamma_j} \frac{V_{j,\phi}}{V_j}, \qquad \lambda_p = H^{\gamma_p} \frac{V_{p,\phi}}{V_p}, \qquad \lambda_g = H^{\gamma_g} \frac{V_{g,\phi}}{V_g}, \qquad \lambda_r = H^{\gamma_r} \frac{V_{r,\phi\phi}}{V_{r,\phi}}, \tag{43}$$

$$\mu_j = \frac{V_j V_{j,\phi\phi}}{(V_{j,\phi})^2}, \qquad \mu_p = \frac{V_p V_{p,\phi\phi}}{(V_{p,\phi})^2}, \qquad \mu_g = \frac{V_g V_{g,\phi\phi}}{(V_{g,\phi})^2}, \qquad \mu_r = \frac{V_{r,\phi} V_{r,\phi\phi\phi}}{(V_{r,\phi\phi})^2}, \tag{44}$$

where α, β_i and $\gamma_i, (i = j, p, g, r)$ are constants.

As in the previous section we specialize to the case where there is no matter excitation present, since we expect the net cosmological constant to dominate the source. Although the source has equation of state $w = -1$, we will find that a judicious choice of *Fab-Four* potentials can mimic a standard cosmological evolution with *any* constant equation of state. In particular, we will show that even in the absence of an explicit matter fluid, and in the presence of a large cosmological constant ρ_Λ, solutions exist that evolve as if the universe is matter dominated i.e. $h = -3/2$ in the language described above.

Substituting (41)-(44) into (11) and (16) we demand that the resulting system of equations are autonomous, which requires all the factors of the Hubble parameter H to scale out of the system. This follows from (11) where the term ρ_Λ is independent of H. Hence all the other terms need to be independent of H as well. Demanding that, we find the following relations

$$\beta_j \;=\; 4 - 2\alpha, \tag{45}$$

$$\beta_p \;=\; 6 - 3\alpha, \tag{46}$$

$$\beta_g \;=\; 2, \tag{47}$$

$$\beta_r \;=\; 4 - \alpha, \tag{48}$$

$$\gamma_j = \gamma_p = \gamma_g = \gamma_r \;=\; -\alpha. \tag{49}$$

The individual Hamiltonian parts are

$$\mathcal{H}_j \;=\; 3x^2 y_j (3 - \sigma^2), \tag{50}$$

$$\mathcal{H}_p \;=\; -3x^3 y_p (5 - 3\sigma^2), \tag{51}$$

$$\mathcal{H}_g \;=\; -6 y_g \left[(1 - \sigma^2) + \lambda_g x \right], \tag{52}$$

$$\mathcal{H}_r \;=\; -24 x y_r (1 - \sigma^2), \tag{53}$$

and combine in (11) to become

$$\mathcal{H} \;=\; \mathcal{H}_j + \mathcal{H}_p + \mathcal{H}_g + \mathcal{H}_r + \rho_\Lambda = 0. \tag{54}$$

Similarly, the individual pieces of the scalar field equation of motion (16) are now

$$E_j^{(\phi)}/(3a^3 H^\alpha) \;=\; 6 x y_j (1 - \sigma^2) + 2(\alpha - 1) h x y_j (1 - \sigma^2) + 2[x y_j (1 - \sigma^2)]' - \lambda_j x^2 y_j (1 - \sigma^2), \tag{55}$$

$$E_p^{(\phi)}/(3a^3 H^\alpha) \;=\; -9 x^2 y_p (1 - \sigma^2) - 3(\alpha - 1) h x^2 y_p (1 - \sigma^2) - 3[x^2 y_p (1 - \sigma^2)]' + \lambda_p x^3 y_p (1 - \sigma^2), \tag{56}$$

$$\begin{aligned} E_g^{(\phi)}/(3a^3 H^\alpha) \;=\; & -6 \lambda_g y_g (1 - \sigma) + 2(1 - \alpha) h \lambda_g y_g (1 - \sigma) - 2[\lambda_g y_g (1 - \sigma)]' \\ & + 2 \mu_g \lambda_g^2 y_g x (1 - \sigma) + 2 \lambda_g y_g (1 - \sigma)^2, \end{aligned} \tag{57}$$

$$E_r^{(\phi)}/(3a^3 H^\alpha) \;=\; -24 y_r (1 + h) \left[-\sigma^2 (1 - \sigma) + \frac{1}{3}(1 - \sigma^3) \right] - 8 y_r \left[-\sigma^2 (1 - \sigma) + \frac{1}{3}(1 - \sigma^3) \right]', \tag{58}$$

and give the full scalar equation of motion

$$E^{(\phi)} = E_j^{(\phi)} + E_p^{(\phi)} + E_g^{(\phi)} + E_r^{(\phi)} = 0. \tag{59}$$

For completeness we can write down the individual pieces of the Euler-Lagrange equations for the scale factor, $E_j^{(a)} = \frac{\partial \mathcal{L}_j}{\partial a} - \frac{d}{dt}\left(\frac{\partial \mathcal{L}_j}{\partial \dot{a}}\right) + \frac{d^2}{dt^2}\left(\frac{\partial \mathcal{L}_j}{\partial \ddot{a}}\right)$, etc. which combine to give the full scale factor equation of motion

$$E^{(a)} = E_j^{(a)} + E_p^{(a)} + E_g^{(a)} + E_r^{(a)} - 3a^2\rho_\Lambda = 0, \tag{60}$$

$$\begin{aligned}
E_j^{(a)} &= 3a^2\left\{-4x^2y_j + 2hx^2y_j - 2(x^2y_j)' + x^2y_j(1-\sigma^2)\right\}, &(61)\\
E_p^{(a)} &= 3a^2\left\{2x^3y_p(3-\sigma^2) - hx^3y_p(3-\sigma^2) + [x^3y_p(3-\sigma^2)]'\right\}, &(62)\\
E_g^{(a)} &= 3a^2\left\{4y_g' + 4y_g(2-h) + 2(\lambda_g x y_g)' - 2h\lambda_g x y_g - 2y_g(1+\sigma^2)\right\}, &(63)\\
E_r^{(a)} &= 3a^2\left\{16xy_r(1-\sigma^2) - 8hxy_r(1-\sigma^2) + 8[xy_r(1-\sigma^2)]'\right\}. &(64)
\end{aligned}$$

Of course, although we have written down the equations for the Hamiltonian constraint, the scalar field and the scale factor, we only require two of these sets as the third can always be obtained as a combination of the other two.

We have nearly completed our derivation of the dynamical system. All that remains is to consider the evolution of the y, λ and μ coefficients in (41) - (44) and σ in (36). These are obtained directly from their definitions. All the λ's evolve as

$$\lambda_i' = \left[-\alpha h + \lambda_i x(\mu_i - 1)\right]\lambda_i, \qquad i = j, p, g, r. \tag{65}$$

The y's evolve according to

$$y_i' = \left[\beta_i h + \lambda_i x\right] y_i, \qquad i = j, p, g, r \tag{66}$$

whereas σ evolves according to

$$\sigma' = -(1+h)\sigma. \tag{67}$$

We note that fixed point solutions for λ_i and y_i correspond to

$$\begin{aligned}
\alpha h &= \lambda_i x(\mu_i - 1) &(68)\\
\beta_i h &= -\lambda_i x &(69)
\end{aligned}$$

Similarly from (67) fixed point solutions for σ exist for $h = -1$ and $\sigma = 0$. Our complete system of equations for investigatating the cosmology is therefore given by (54), (60), (59), (65), (66) and (67). We also have the definitions (36), (41) - (44) and the conditions (45) - (49).

In order to obtain closed form solutions, it is convenient to assume that **all the μ_i are constant**, which generically corresponds to power law potentials

$$\begin{aligned}
V_i &= V_{0i}\phi^{1/(1-\mu_i)}, \qquad i = j, p, g, &(70)\\
V_{r,\phi} &= V_{0r}\phi^{1/(1-\mu_r)}. &(71)
\end{aligned}$$

The special value of $\mu_i = 1$ corresponds to the case where the potentials are exponential. We can now make some immediate progress: using (68) and (69) at the fixed point we show that

$$\alpha = \beta_i(1-\mu_i) \tag{72}$$

By further imposing (45) to (48), we see that the powers in the potentials (70) and (71) are given by

$$\frac{1}{1-\mu_j} = \frac{\beta_j}{\alpha} = \frac{4}{\alpha} - 2 \tag{73}$$

$$\frac{1}{1-\mu_p} = \frac{\beta_p}{\alpha} = \frac{6}{\alpha} - 3 \tag{74}$$

$$\frac{1}{1-\mu_g} = \frac{\beta_g}{\alpha} = \frac{2}{\alpha} \tag{75}$$

$$\frac{1}{1-\mu_r} = \frac{\beta_r}{\alpha} = \frac{4}{\alpha} - 1 \tag{76}$$

We can also integrate (65) to give

$$\lambda_i = \frac{1}{1-\mu_i} V_{0i}^{1-\mu_i} y_i^{\mu_i - 1}, \qquad i = j, p, g, r \tag{77}$$

A. $\sigma = 0$ fixed point: vanishing spatial curvature

We shall begin by studying the fixed point $\sigma = 0$ because it corresponds to the situation where spatial curvature is sub-dominant, and so we expect the early behaviour to be closely matched by such fixed points even though σ may not strictly vanish. Now (once again under the assumption that all the μ_i are well-defined and constant), we can make use of (77) and (68) to obtain

$$y_i = V_{0i}[(1-\mu_i)\lambda_i x/x]^{1/(\mu_i - 1)}, \tag{78}$$

$$= V_{0i}(-\alpha h/x)^{-\beta_i/\alpha}. \tag{79}$$

We therefore have y_i in terms of h and x once we have chosen a specific α, from which the μ_i are derived and hence the potentials determined. It allows us to replace the y_i terms in the scale factor, and the scalar equations of motion at the fixed-point (where everything is constant), which leads to two equations for the variables, x and h. The Hamiltonian is not an independent equation but could have been used instead of say the scale factor equation of motion.

Once we reach the fixed point, and using (45)-(48), and (69), the scalar field equation of motion (59) becomes

$$2xy_j(3+h) - 3x^2 y_p(3+h) - 2\lambda_g y_g(2+h) - 8y_r(1+h) = 0, \tag{80}$$

which in turn becomes upon using (79)

$$-3(3+h)V_{0p}(-\alpha h)^{2-2/\alpha}x^{2/\alpha} - 2V_{0j}\alpha h(3+h) - 8V_{0r}(1+h) + 4h(2+h)V_{og}(-\alpha h)^{-1+2/\alpha}x^{-2/\alpha} = 0 \tag{81}$$

We could equivalently write this as

$$A(x^{2/\alpha})^2 + B(x^{2/\alpha}) + C = 0, \tag{82}$$

where

$$A = -3(3+h)V_{0p}(-\alpha h)^{2-2/\alpha}, \tag{83}$$

$$B = -2V_{0j}\alpha h(3+h) - 8V_{0r}(1+h), \tag{84}$$

$$C = 4h(2+h)V_{0g}(-\alpha h)^{-1+2/\alpha}, \tag{85}$$

and solve the quadratic to find $x(\alpha, h, V_{0j}/V_{0p}, V_{0g}/V_{0p}, V_{0r}/V_{0p})$. We also have the following for the scale-factor equation of motion (60) and Hamiltonian constraint (54) respectively

$$(2h-3)x^2 y_j + 3(2-h)x^3 y_p + 2(3-2h+2h^2)y_g + 8(2-h)xy_r = \rho_\Lambda, \tag{86}$$

$$9x^2 y_j - 15x^3 y_p - 6y_g\,[1+\lambda_g x] - 24xy_r = -\rho_\Lambda. \tag{87}$$

In particular the Hamiltonian (87) becomes a cubic equation in $x^{2/\alpha}$

$$15\alpha^3 h^3 V_{0p}\left(-\frac{\alpha h}{x}\right)^{-6/\alpha} + 3h\alpha[3h\alpha V_{0j} + 8V_{0r}]\left(-\frac{\alpha h}{x}\right)^{-4/\alpha} - 6(1-2h)V_{0g}\left(-\frac{\alpha h}{x}\right)^{-2/\alpha} + \rho_\Lambda \;=\; 0 \quad (88)$$

Now, any self tuning solution should be such that the parameters in the potential, α, $V_{0i}, (i = j, p, r, g)$ are independent of ρ_Λ, in other words they should not be fine tuned for a particular value of ρ_Λ. This implies that the solution for $x^{2/\alpha}$ in (82) will be independent of ρ_Λ as there is no ρ_Λ term in it. However, this would then be inconsistent when substituted into the Hamiltonian constraint (88) where a ρ_Λ term is present. In order to avoid this potential inconsistency we must have that each of A, B and C vanish in (82) because it then does not give an equation for $x^{2/\alpha}$, and so x is allowed to depend on ρ_Λ in (88).

We can recover various results from (82) corresponding to different scale-factor evolutions (determined by h (38)) by considering the vanishing of various terms. We list some interesting examples in table I. The first

TABLE I: Examples of interesting cosmological behaviour for various fixed points with $\sigma = 0$.

Case	cosmological behaviour	$V_j(\phi)$	$V_p(\phi)$	$V_g(\phi)$	$V_r(\phi)$
Stiff fluid	$H^2 \propto 1/a^6$	$c_1\phi^{\frac{4}{\alpha}-2}$	$c_2\phi^{\frac{6}{\alpha}-3}$	0	0
Radiation	$H^2 \propto 1/a^4$	$c_1\phi^{\frac{4}{\alpha}-2}$	0	$c_2\phi^{\frac{2}{\alpha}}$	$-\frac{\alpha^2}{8}c_1\phi^{\frac{4}{\alpha}}$
Curvature	$H^2 \propto 1/a^2$	0	0	0	$c_1\phi^{\frac{4}{\alpha}}$
Arbitrary	$H^2 \propto a^{2h}, \quad h \neq 0$	$c_1(1+h)\phi^{\frac{4}{\alpha}-2}$	0	0	$-\frac{\alpha^2}{16}h(3+h)c_1\phi^{\frac{4}{\alpha}}$

three of these are consistent with the results of the previous section. However, perhaps the most interesting solution is that last one, labelled "Arbitrary". This corresponds to any cosmological evolution consistent with a power law expansion $a \propto t^{-1/h}$, including a matter dominated universe ($h = -3/2$), and inflationary expansion ($-1 < h < 0$).

We will discuss the behaviour of these solutions in more detail in section V. In particular we will switch the spatial curvature back on, and use numerical simulations to demonstrate how these various cosmological behaviours dominate at early times before giving in to self tuning at late times[2], and so an asymptotically Milne Universe. We will also show that the most interesting of these solutions – the matter-like cosmology – suffers from a rapid gradient instability at the level of cosmological perturbations. This is unfortunate, but all is not lost. In the following section we obtain a new class of matter-like scaling solutions that exist for $\rho_\Lambda = 0$. This may seem like a strange thing to do given that the *Fab-Four* was introduced to deal with a large cosmological constant, however, the analysis of the forthcoming section is simply a means to an end. As we will see in section V, in certain cases, these solutions will not dramatically alter their behaviour when ρ_Λ is turned on, and, more importantly, they are stable.

B. $\sigma = 0$ fixed point with $\rho_\Lambda = 0$: vanishing curvature and cosmological constant

Setting $\rho_\Lambda = 0$ in the Hamiltonian constraint (11) implies that for fixed point solutions to exist the individual terms (12)-(15) no longer have to be time-independent. They can all scale with the Hubble parameter, for instance, as long as they scale in the same way. This then has a knock-on effect on the allowed solutions as we shall now see. In terms of the scaling parameters, the individual components of the

[2] Such late time behaviour only applies to matter and radiation, but not inflation

Hamiltonian (50)-(53) are replaced by

$$\mathcal{H}_j = 3x^2y_j(3-\sigma^2)H^{4-\beta_j-2\alpha}, \quad (89)$$
$$\mathcal{H}_p = -3x^3y_p(5-3\sigma^2)H^{6-3\alpha-\beta_p}, \quad (90)$$
$$\mathcal{H}_g = -6y_g\left[(1-\sigma^2)H^{2-\beta_g}+\lambda_g x H^{2-\beta_g-\alpha-\gamma_g}\right], \quad (91)$$
$$\mathcal{H}_r = -24xy_r(1-\sigma^2)H^{4-\alpha-\beta_r}, \quad (92)$$

where the explicit H dependence is included. Now if we demand that all the individual terms in the Hamiltonian scale as H^n (which, for constant h, is equivalent to $H^n \sim a^{nh}$) then we obtain the following constraints, replacing (45)-(49)

$$\beta_j = 4-2\alpha-n, \quad (93)$$
$$\beta_p = 6-3\alpha-n, \quad (94)$$
$$\beta_g = 2-n, \quad (95)$$
$$\beta_r = 4-\alpha-n, \quad (96)$$
$$\gamma_j=\gamma_p=\gamma_g=\gamma_r = -\alpha. \quad (97)$$

The scalar field equations of motion (55)-(58) are replaced by

$$E_j^{(\phi)}/(3a^3H^{\alpha+n}) = 6xy_j(1-\sigma^2)+2(\alpha+n-1)hxy_j(1-\sigma^2)+2[xy_j(1-\sigma^2)]'-\lambda_j x^2y_j(1-\sigma^2), \quad (98)$$
$$E_p^{(\phi)}/(3a^3H^{\alpha+n}) = -9x^2y_p(1-\sigma^2)-3(\alpha+n-1)hx^2y_p(1-\sigma^2)-3[x^2y_p(1-\sigma^2)]' + \lambda_p x^3y_p(1-\sigma^2), \quad (99)$$
$$E_g^{(\phi)}/(3a^3H^{\alpha+n}) = -6\lambda_g y_g(1-\sigma)-2(\alpha+n-1)h\lambda_g y_g(1-\sigma)-2[\lambda_g y_g(1-\sigma)]' + 2\mu_g\lambda_g^2 y_g x(1-\sigma)+2\lambda_g y_g(1-\sigma)^2, \quad (100)$$
$$E_r^{(\phi)}/(3a^3H^{\alpha+n}) = -24y_r(1+h)\left[-\sigma^2(1-\sigma)+\frac{1}{3}(1-\sigma^3)\right]-8y_r\left[-\sigma^2(1-\sigma)+\frac{1}{3}(1-\sigma^3)\right]', \quad (101)$$

the scale factor equations (61)-(64) become

$$E_j^{(a)}/(3a^2H^n) = \left\{-4x^2y_j+2(1-n)hx^2y_j-2(x^2y_j)'+x^2y_j(1-\sigma^2)\right\}, \quad (102)$$
$$E_p^{(a)}/(3a^2H^n) = \left\{2x^3y_p(3-\sigma^2)-(1-n)hx^3y_p(3-\sigma^2)+[x^3y_p(3-\sigma^2)]'\right\}, \quad (103)$$
$$E_g^{(a)}/(3a^2H^n) = \left\{4y_g'+4y_g(2-(1-n)h)+2(\lambda_g xy_g)'-2(1-n)h\lambda_g xy_g-2y_g(1+\sigma^2)\right\}, \quad (104)$$
$$E_r^{(a)}/(3a^2H^n) = \left\{16xy_r(1-\sigma^2)-8(1-n)hxy_r(1-\sigma^2)+8[xy_r(1-\sigma^2)]'\right\}, \quad (105)$$

and, for completeness, the Hamiltonian constraint remains as before (recall we have ensured the time dependence in H factors out)

$$3x^2y_j(3-\sigma^2)-3x^3y_p(5-3\sigma^2)-6y_g\left[(1-\sigma^2)+\lambda_g x\right]-24xy_r(1-\sigma^2)=0. \quad (106)$$

The results obtained previously for the λ's, y's and σ (65)-(69) still apply, although of course with the new values for the β coefficients. We now look for $\sigma=0$ fixed point solutions in order to understand the early-time behaviour. The Hamiltonian constraint (106) becomes

$$9x^2y_j-15x^3y_p-6y_g\left[1+\lambda_g x\right], -24xy_r=0, \quad (107)$$

and the scalar equation of motion (98)-(101) becomes

$$6xy_j+2(\alpha+n-1)hxy_j-\lambda_j x^2y_j-9x^2y_p-3(\alpha+n-1)hx^2y_p + \lambda_p x^3y_p-4\lambda_g y_g-2(\alpha+n-1)h\lambda_g y_g+2\mu_g\lambda_g^2y_g x-8y_r(1+h)=0. \quad (108)$$

We can follow the route taken in the previous subsection and use the fact that for all four potentials $(i = j, p, g, r)$ (68) and (69) still hold, giving

$$\Rightarrow \alpha/\beta_i \;=\; 1-\mu_i, \tag{109}$$

which leaves (108) as

$$[6+(n+2)h)]xy_j - [9+(3+2n)h]x^2y_p - 2\lambda_g y_g[2+h] - 8y_r(1+h) = 0. \tag{110}$$

Now, if we take $\mu = const$ then we can use (79) to rewrite the Hamiltonian (107) as

$$-6[1+(n-2)h]V_{0g}\left(-\frac{\alpha h}{x}\right)^{4/\alpha} + [9\alpha^2h^2V_{0j} + 24\alpha h V_{0r}]\left(-\frac{\alpha h}{x}\right)^{2/\alpha} + 15\alpha^3h^3V_{0p} = 0. \tag{111}$$

Similarly the scalar equation of motion (110) may be written as

$$\begin{aligned} &2(2+h)(2-n)hV_{0g}\left(-\frac{\alpha h}{x}\right)^{4/\alpha} + \left\{[6+(n+2)h)]\alpha^2h^2V_{0j} + 8(1+h)\alpha h V_{0r}\right\}\left(-\frac{\alpha h}{x}\right)^{2/\alpha} \\ &+[9+(3+2n)h]\alpha^3h^3V_{0p} = 0. \end{aligned} \tag{112}$$

If we now define the variables

$$\tilde{V}_{0j} \;=\; \alpha^2h^2V_{0j},\; \tilde{V}_{0p} = \alpha^3h^3V_{0p},\; \tilde{V}_{0g} = V_{0g},\; \tilde{V}_{0r} = \alpha h V_{0r}, \tag{113}$$

$$\tilde{X} \;=\; (-\alpha h/x)^{2/\alpha}, \tag{114}$$

then the Hamiltonian equation (111) and the scalar equation of motion (112) become

$$-6[1+(n-2)h]\tilde{V}_{0g}\tilde{X}^2 + [9\tilde{V}_{0j} + 24\tilde{V}_{0r}]\tilde{X} + 15\tilde{V}_{0p} \;=\; 0, \tag{115}$$

$$2(2+h)(2-n)h\tilde{V}_{0g}\tilde{X}^2 + \left\{[6+(n+2)h]\tilde{V}_{0j} + 8(1+h)\tilde{V}_{0r}\right\}\tilde{X} + [9+(3+2n)h]\tilde{V}_{0p} \;=\; 0. \tag{116}$$

Our aim now is to find solutions of these equations. On the surface it would seem that we can just solve for $\tilde{X}$ and n, and pick h and the $\tilde{V}_{0\#}$ at will. In particular, for a matter dominated epoch we would pick $h = -3/2$. However, it is worth pausing for a moment to think about our ultimate goal. We would like any such solution to be robust against switching ρ_Λ back on. To see how this might be possible, it proves useful to introduce

$$\hat{n} \;=\; hn, \tag{117}$$

since then, for constant h, we have $\mathcal{H} \sim H^n \sim a^{\hat{n}}$. So, if we can find solutions for positive $\hat{n}$, the correction to the Hamiltonian from switching ρ_Λ back on, $\rho_\Lambda a^{-\hat{n}}$, may be expected to become less significant with expansion, meaning that the $\rho_\Lambda = 0$ solution was indeed worth finding. At this point it also proves convenient to fix the freedom we have in re-defining the scalar field, by choosing the parameter α such that

$$\alpha h = -1. \tag{118}$$

We may then determine the powers of ϕ that appear in the scalar potentials (70), (71)

$$\frac{1}{1-\mu_j} \;=\; \beta_j/\alpha = \frac{4-n}{\alpha} - 2 = \hat{n} - (4h+2), \tag{119}$$

$$\frac{1}{1-\mu_p} \;=\; \beta_p/\alpha = \frac{6-n}{\alpha} - 3 = \hat{n} - (6h+3), \tag{120}$$

$$\frac{1}{1-\mu_g} \;=\; \beta_g/\alpha = \frac{2-n}{\alpha} = \hat{n} - 2h, \tag{121}$$

$$\frac{1}{1-\mu_r} \;=\; \beta_r/\alpha = \frac{4-n}{\alpha} - 1 = \hat{n} - (4h+1). \tag{122}$$

We shall now focus on reproducing a matter epoch, so we plug $h = -3/2$ and $\alpha = 2/3$ into (115) and (116). This gives

$$-6(\hat{n}+4)V_{0g}\tilde{X}^2 + [9V_{0j} - 24V_{0r}]\tilde{X} - 15V_{0p} = 0 \tag{123}$$

$$-(\hat{n}+3)V_{0g}\tilde{X}^2 + [(\hat{n}+3)V_{0j} + 4V_{0r}]\,\tilde{X} - \left(\frac{9}{2} + 2\hat{n}\right)V_{0p} = 0 \tag{124}$$

We want these two equations to have a common root. Although we will miss the full spectrum of possibilities, it is convenient and cleaner to impose the stronger constraint that the two equations have *two* common roots. This requires that the following equations hold for some constant χ

$$6\chi(\hat{n}+4)V_{0g} = (\hat{n}+3)V_{0g}, \tag{125}$$

$$\chi[9V_{0j} - 24V_{0r}] = (\hat{n}+3)V_{0j} + 4V_{0r}, \tag{126}$$

$$15\chi V_{0p} = \left(\frac{9}{2} + 2\hat{n}\right)V_{0p}. \tag{127}$$

Now if $V_{0p}, V_{0g} \neq 0$ then it follows from (125) and (127) that $\hat{n} = -\frac{3}{2}, -\frac{7}{2}$. However, as explained above, we are only interested in $\hat{n} > 0$, so we assume that one of V_{0p}, V_{0g} vanishes. The two possibilities are presented in table II. In each case, either Paul or George is switched on/off, and the interplay of John and Ringo gives

TABLE II: Examples of matter-like cosmological fixed points with $\sigma = 0$ and $\rho_\Lambda = 0$.

Case	cosmological behaviour	$V_j(\phi)$	$V_p(\phi)$	$V_g(\phi)$	$V_r(\phi)$
Matter I	$H^2 \propto 1/a^3$	$c_1\phi^{\hat{n}+4}$	$c_2\phi^{\hat{n}+6}$	0	$\frac{2\hat{n}-3}{16(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6}$
Matter II	$H^2 \propto 1/a^3$	$c_1\phi^{\hat{n}+4}$	0	$c_2\phi^{\hat{n}+3}$	$-\frac{(\hat{n}+3)(2\hat{n}+5)}{8(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6}$

rise to a cosmology that mimics a matter dominated epoch. This is true for any value of $\hat{n}$, and in particular, for $\hat{n} > 0$. We will see in the next section that these solutions are indeed robust against switching on ρ_Λ, and there exists large regions of parameter space $(\hat{n}, c_1, c_2)$ for which their cosmological perturbations are stable.

V. SUMMARY OF COSMOLOGICAL SOLUTIONS

The goal of this paper was to establish whether or not the *Fab-Four* could, in principle, accommodate a consistent cosmological history. In particular, is the *Fab-Four* consistent with an early period of inflation, followed by a radiation and matter dominated epoch, during which nucleosythesis takes place and structures begin to form? At late times, we want another period of inflation, before self-tuning kicks in and the Universe enters a late time Milne solution, whatever the value of the cosmological constant. Our dynamical systems analysis, allied with the numerical solutions to be presented shortly, demonstrates that each desired epoch can be individually realised with a judicious choice of potentials. It is not too difficult to imagine that one could, in principle, combine the various choices in such a way that one particular choice dominates the dynamics at one particular epoch, thereby reproducing the desired cosmic history in its entirety. Recall that the cosmological constant is always assumed to be large, dominating over any other sources. Including extra sources explicitly is straightforward as we know the scaling behaviour of both radiation and matter with scale factor evolution.

Having obtained desirable solutions, we should also demonstrate that they are stable to perturbations, or at least stable enough that they will survive for the e-foldings necessary for structures to form. Scalar-tensor theories can be plagued with ghost and gradient instabilities (see [4] for a review of the subject), which is one of the main reasons it is proving so challenging to develop successful modified theories of gravity. This involves lengthy calculations in each case, and for that reason we restrict attention, for now, to the epoch of

greatest interest – matter domination. We will see that the matter epoch is perturbatively stable for a large class of cases.

We will now summarise how each desired epoch can be reproduced within the *Fab-Four*, reinforcing our analytic calculations with numerical simulations of the full system. In each case we will plot the evolution of the deceleration parameter, $q = -a\ddot{a}/\dot{a}^2$, which is expected to give $q < 0$ (inflation), $q = 1$ (radiation), $q = 0.5$ (matter) and $q = 0$ (self-tuning). As promised, the matter epoch will also include a discussion of stability.

A. The inflationary epoch

It is natural ask how any self-tuning scenario can accommodate inflation, be it early or late. The point is that self-tuning can be a late time attractor, and that inflation can happen beforehand. Clearly this would be perfectly consistent with what we observe. In section IV A we saw how power law inflation, $a \sim t^p$, with $p > 1$ could be achieved for arbitrary ρ_Λ with the choice:

$$V_j(\phi) = c_1 \left(\frac{p-1}{p}\right) \phi^{\frac{4}{p}-2}, \qquad V_p(\phi) = V_g(\phi) = 0, \qquad V_r(\phi) = \frac{3p-1}{16} c_1 \phi^{\frac{4}{p}}, \tag{128}$$

where we have used the fact that $p = -1/h$, and have fixed the freedom to redefine the scalar field by setting $\alpha h = -1$. For vanishing spatial curvature, the field equations (22) and (23) can be straightforwardly solved to give

$$\phi = \nu a, \qquad H^2 = \sqrt{\frac{p\rho_\Lambda}{3c_1(3p+1)}} (\nu a)^{-2/p}, \tag{129}$$

where ν is an arbitrary constant. The inflationary case actually presents a qualitatively different behaviour to the matter and radiation solution, as could have been guessed from (67). In (67) we see that one may expect $\sigma = 0$ to be a repeller fixed-point for $1 + h < 0$, such as matter and radiation, but an attractor for $1 + h > 0$. Although this is rather naive, as there are many more variables to consider, this is indeed what is observed. Switching on spatial curvature and performing the full evolution drives the system to the $\sigma = 0$ inflationary solution, as seen in Fig. 1. Of course, in a more complicated scenario in which potentials are

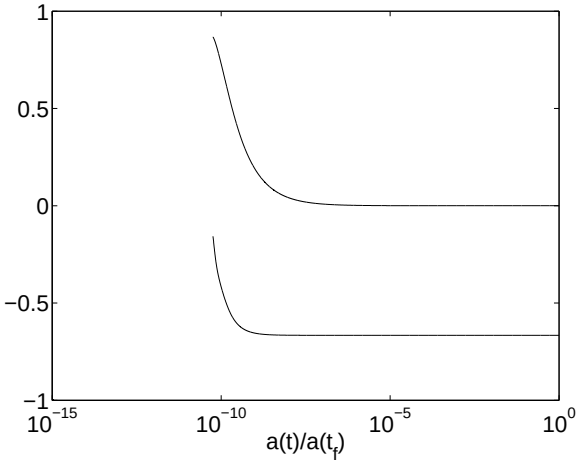

FIG. 1: Plot of the deceleration parameter, q, (lower curve) and 100σ (upper curve) for the inflationary case for $p = 3$. The parameters used were $k = -10$, $\rho_\Lambda = 1000$, $\phi_{initial} = 0.1$, $c_1 = 1.5$

"sewn together" so that inflation gives way to radiation one expects self-tuning to dominate at very late times.

B. The radiation epoch

In section IV A, we found that for arbitrary ρ_Λ the following potentials will mimic a radiation dominated Universe,

$$V_j(\phi) = c_1\phi^6, \qquad V_p(\phi) = 0, \qquad V_g(\phi) = c_2\phi^4, \qquad V_r(\phi) = -\frac{c_1}{32}\phi^8, \tag{130}$$

with a vanishing spatial curvature solution of

$$\phi = \nu a, \qquad H^2 = \frac{c_2}{c_1}\left[1 \pm \sqrt{1 - \frac{\rho_\Lambda c_1}{15c_2}}\right](\nu a)^{-4}, \tag{131}$$

where ν is an arbitrary constant. Note that as $c_1 \to 0$ the negative root above has a well defined limit. This corresponds to the case where only George is turned on. We could easily have guessed that this would mimic radiation since the scalar equation of motion imposes the constraint $R = 0$. This is equivalent to saying that the trace of the effective energy momentum tensor vanishes.

When we reintroduce the spatial curvature, self-tuning kicks in. This is explicitly demonstrated by the numerical solutions presented in figure 2.

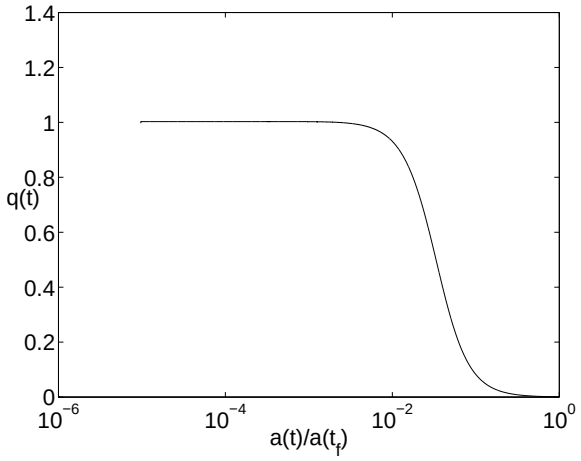

FIG. 2: Plot of the deceleration parameter for an initially radiation-like solution, with $k = -0.1$, $\rho_\Lambda = 1000$, $\phi_{initial} = 0.1$, $c_1 = -0.5$.

C. The matter epoch

We finally turn to the matter epoch. We have identified three classes of potential that can mimic a matter dominated universe. Let us consider the first two of these, dubbed "Matter I" and "Matter II", and identified in section IV B for vanishing curvature and cosmological constant. The "Matter I" potentials have vanishing V_g, and are given by

$$V_j(\phi) = c_1\phi^{\hat{n}+4}, \qquad V_p(\phi) = c_2\phi^{\hat{n}+6}, \qquad V_g(\phi) = 0, \qquad V_r(\phi) = \frac{2\hat{n}-3}{16(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6} \tag{132}$$

For vanishing spatial curvature and cosmological constant, this admits a solution,

$$\phi = \nu a, \qquad H^2 = \left[\frac{2\hat{n}+9}{2(2\hat{n}+7)}\right]\frac{c_1}{c_2}(\nu a)^{-3} \tag{133}$$

where ν is an arbitrary constant. The "Matter II" potentials have vanishing V_p, and are given by

$$V_j(\phi) = c_1\phi^{\hat{n}+4}, \qquad V_p(\phi) = 0, \qquad V_g(\phi) = c_2\phi^{\hat{n}+3}, \qquad V_r(\phi) = -\frac{(\hat{n}+3)(2\hat{n}+5)}{8(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6}. \tag{134}$$

This time, for vanishing spatial curvature and cosmological constant, we have the solution,

$$\phi = \nu a, \qquad H^2 = \left[\frac{2(2\hat{n}+7)}{2\hat{n}+9}\right]\frac{c_2}{c_1}(\nu a)^{-3}, \tag{135}$$

where ν is an arbitrary constant. Note that this solution is not well defined as $c_1 \to 0$, when we expect to recover a radiation-like Universe.

Of course, these solutions are only valid when $\rho_\Lambda = 0$, which goes against the spirit of the *Fab-Four* and self-tuning. What happens when we switch ρ_Λ back on? To get an idea, let us perturb about these solutions and compute the Hamiltonian (22) and scalar equation of motion (23) to leading order. To this end, we set

$$\phi = \nu a + \delta\phi(N), \qquad H^2 = \frac{m^2}{a^3} + \delta H^2(N), \tag{136}$$

with

$$m^2 = \begin{cases} \left[\frac{2\hat{n}+9}{2(2\hat{n}+7)}\right]\frac{c_1}{c_2}\nu^{-3} & \text{Matter I} \\ \left[\frac{2(2\hat{n}+7)}{2\hat{n}+9}\right]\frac{c_2}{c_1}\nu^{-3} & \text{Matter II} \end{cases} \tag{137}$$

and expand (22) and (23) to leading order in δ. The result is

$$\delta\mathcal{H}_j + \delta\mathcal{H}_p + \delta\mathcal{H}_g + \delta\mathcal{H}_r = -\rho_\Lambda. \tag{138}$$

$$\delta\tilde{E}_j^{(\phi)} + \delta\tilde{E}_p^{(\phi)} + \delta\tilde{E}_g^{(\phi)} + \delta\tilde{E}_r^{(\phi)} = 0. \tag{139}$$

where

$$\delta\mathcal{H}_j = \mathcal{H}_j\left[2\frac{\delta H^2}{H^2} + (\hat{n}+6)\frac{\delta\phi}{\phi} + 2\left(\frac{\delta\phi}{\phi}\right)'\right]. \tag{140}$$

$$\delta\mathcal{H}_p = \mathcal{H}_p\left[3\frac{\delta H^2}{H^2} + (\hat{n}+9)\frac{\delta\phi}{\phi} + 3\left(\frac{\delta\phi}{\phi}\right)'\right]. \tag{141}$$

$$\delta\mathcal{H}_g = \mathcal{H}_g\left[\frac{\delta H^2}{H^2} + (\hat{n}+3)\frac{\delta\phi}{\phi} + \left(\frac{\hat{n}+3}{\hat{n}+4}\right)\left(\frac{\delta\phi}{\phi}\right)'\right]. \tag{142}$$

$$\delta\mathcal{H}_r = \mathcal{H}_r\left[2\frac{\delta H^2}{H^2} + (\hat{n}+6)\frac{\delta\phi}{\phi} + \left(\frac{\delta\phi}{\phi}\right)'\right], \tag{143}$$

and

$$\delta\tilde{E}_j^{(\phi)} = \delta\left(E_j^{(\phi)}\dot{\phi}/Ha^3\right) = \frac{\mathcal{H}_j}{3}\left[3\left(\frac{\delta H^2}{H^2}\right)' + 2(\hat{n}+3)\frac{\delta H^2}{H^2} + 2\left(\frac{\delta\phi}{\phi}\right)'' + 3(\hat{n}+4)\left(\frac{\delta\phi}{\phi}\right)' + (\hat{n}+3)(\hat{n}+6)\frac{\delta\phi}{\phi}\right], \tag{144}$$

$$\delta\tilde{E}_p^{(\phi)} = \delta\left(E_p^{(\phi)}\dot{\phi}/Ha^3\right) = \frac{2\mathcal{H}_p}{5}\left[\frac{15}{4}\left(\frac{\delta H^2}{H^2}\right)' + 3\left(\hat{n}+\frac{9}{4}\right)\frac{\delta H^2}{H^2} + 3\left(\frac{\delta\phi}{\phi}\right)'' + \left(4\hat{n}+\frac{63}{4}\right)\left(\frac{\delta\phi}{\phi}\right)' + \left(\hat{n}+\frac{9}{4}\right)(\hat{n}+9)\frac{\delta\phi}{\phi}\right], \tag{145}$$

$$\delta\tilde{E}_g^{(\phi)} = \delta\left(E_g^{(\phi)}\dot{\phi}/Ha^3\right) = \frac{\mathcal{H}_g}{2}\left(\frac{\hat{n}+3}{\hat{n}+4}\right)\left[\left(\frac{\delta H^2}{H^2}\right)' + \frac{\delta H^2}{H^2} + \left(\frac{\delta\phi}{\phi}\right)' + (\hat{n}+3)\frac{\delta\phi}{\phi}\right], \tag{146}$$

$$\delta\tilde{E}_r^{(\phi)} = \delta\left(E_r^{(\phi)}\dot{\phi}/Ha^3\right) = \frac{\mathcal{H}_r}{2}\left[\left(\frac{\delta H^2}{H^2}\right)' - 2\frac{\delta H^2}{H^2} - \left(\frac{\delta\phi}{\phi}\right)' - (\hat{n}+6)\frac{\delta\phi}{\phi}\right]. \tag{147}$$

Note that the unperturbed Hamiltonian densities vary as $\mathcal{H} \propto a^{\hat{n}}$, which suggests that even a large cosmological constant may be regarded as small perturbation, provided $\rho_\Lambda/a^{\hat{n}} \ll 1$. We now use (138) to find $\delta H^2/H^2$, and substitute the result into (139). In each case we obtain

$$\left(\frac{\delta\phi}{\phi}\right)'' + \left(\hat{n}+\frac{9}{2}\right)\left(\frac{\delta\phi}{\phi}\right)' = f(\hat{n};c_1,c_2)\frac{\rho_\Lambda}{(\nu a)^{\hat{n}}}, \tag{148}$$

where

$$f(\hat{n};c_1,c_2) = \begin{cases} -\frac{2(2\hat{n}+27))(2\hat{n}+7)^3c_2^2}{(2\hat{n}+9)^2(4\hat{n}^2+28\hat{n}+9)c_1^3} & \text{Matter I} \\ -\frac{(2\hat{n}+9)^2(2\hat{n}^2+5\hat{n}-9)c_1}{16(2\hat{n}+7)(4\hat{n}^3+32\hat{n}^2+71\hat{n}+27)c_2^2} & \text{Matter II} \end{cases} \tag{149}$$

This is straightforwardly solved to give

$$\frac{\delta\phi}{\phi} = A_1 + \frac{A_2}{a^{\hat{n}+\frac{9}{2}}} - \frac{2f}{9\hat{n}}\frac{\rho_\Lambda}{(\nu a)^{\hat{n}}}, \tag{150}$$

where A_1 and A_2 are integration constants. It immediately follows that

$$\frac{\delta H^2}{H^2} = B_1 + \frac{B_2}{a^{\hat{n}+\frac{9}{2}}} + g\frac{\rho_\Lambda}{(\nu a)^{\hat{n}}}, \tag{151}$$

where the constants B_1, B_2 and g are related to A_1, A_2 and f respectively. It is now clear that for $\hat{n} > 0$, $c_1, c_2 \neq 0$, the solutions (133) and (135) are late time attractors for vanishing curvature, even when we switch on ρ_Λ. This view is reinforced by the plots shown in figures 3 and 4. In each case, the evolution mimics a matter dominated epoch for a long time even in the presence of a cosmological constant. When we also include curvature in the numerical simulation, the solution ultimately gives in to self tuning and asymptotes to a Milne universe. As we will see in the next section, one can choose $\hat{n} > 0, c_1$ and c_2 such that we have stable cosmological perturbations for Matter I and Matter II.

The third class of potentials to mimic matter domination, which we dub "Matter III", are given by

$$V_j(\phi) = -\frac{1}{2}c_1\phi^4, \qquad V_p(\phi) = V_g(\phi) = 0, \qquad V_r(\phi) = \frac{1}{16}c_1\phi^6, \tag{152}$$

and follow from the "arbitrary" row of table I, giving a matter-like solution for arbitrary ρ_Λ when $h = -3/2$ and $\sigma = 0$. The explicit solution is

$$\phi = \nu a, \qquad H^2 = \sqrt{\frac{2\rho_\Lambda}{81c_1}}(\nu a)^{-3}, \tag{153}$$

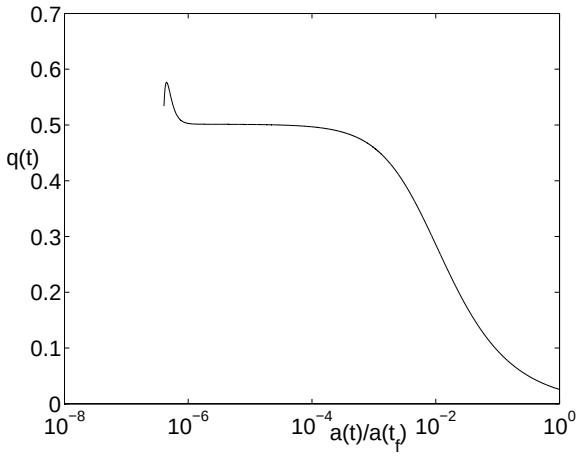

FIG. 3: Plot of the deceleration parameter for the Matter I solution, with $k = -10^{-4}$, $\phi_{initial} = 3.0$, $\rho_\Lambda = 1$, $\hat{n} = 6$, $c_1 = 1$, $c_2 = 10$, consistent with stable cosmological perturbations, as shown in section V C 1.

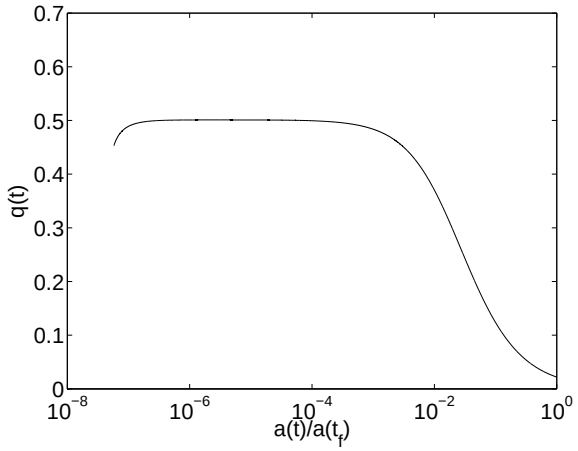

FIG. 4: Plot of the deceleration parameter for the Matter II solution, with $k = -0.1$, $\phi_{initial} = 0.1$, $\rho_\Lambda = 1$, $\hat{n} = 2$, $c_1 = 1$, $c_2 = 8$, consistent with stable cosmological perturbations, as shown in section V C 1.

where ν is an arbitrary constant. The numerical solution with non-vanishing curvature is shown in figure 5. Whilst this solution seems well behaved at the level of FLRW cosmology, we will see that it is unstable under cosmological perturbations.

In summary, then, we have found three classes of potential that mimic a matter dominated cosmology, even when the source is dominated by a cosmological constant. For the Matter I and Matter II potentials, we can choose parameters such that the solutions are stable under cosmological perturbations. These solutions are remarkable. The *Fab-Four* potentials have forced the scalar to screen the pressure component of the cosmological constant before it screens the energy density. This allows for an intermediate, and in some cases, pathology-free, period resembling a matter dominated cosmology, even in the absence of a pressureless source. At the latest times, the energy component of the cosmological constant is also screened and the solutions evolve to an asymptotically Milne universe, which is, of course, equivalent to a patch of Minkowski space.

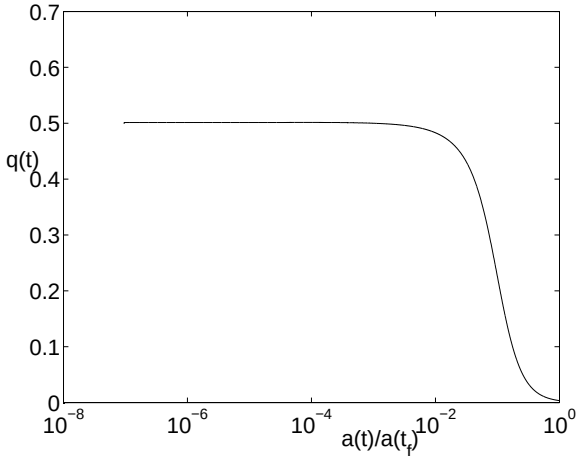

FIG. 5: Plot of the deceleration parameter for an initially Matter III solution, with $k = -0.1$, $\rho_\Lambda = 1000$, $\phi_{initial} = 0.1$, $c_1 = 1$.

1. *Stability during matter epoch*

As promised, we will now consider cosmological perturbations about each class of matter solution. Since we are interested in the phase prior to self-tuning, we shall restrict attention to vanishing curvature, and the solutions given by (133), (135) and (153). Vacuum perturbations about spatially flat cosmologies were studied in detail for Horndeski's theory in [10]. Working in unitary gauge, the scalar takes on its background value, $\phi = \phi(t)$, whereas the line element is given by

$$ds^2 = -N^2 dt^2 + \gamma_{ij}(dx^i + N^i dt)(dx^j + N^j dt), \tag{154}$$

with

$$N = 1 + \hat{\alpha}, \qquad N_i = \partial_i \hat{\beta}, \qquad \gamma_{ij} = a^2(t) e^{2\zeta} \left(\delta_{ij} + h_{ij}\right). \tag{155}$$

The quadratic action for tensor perturbations is found to be

$$S_{tensor} = \frac{1}{8} \int dt d^3x a^3 \left[\mathcal{G}_T \dot{h}_{ij}^2 - \frac{\mathcal{F}_T}{a^2} (\vec{\nabla} h_{ij})^2 \right], \tag{156}$$

where $\mathcal{G}_T$ and $\mathcal{F}_T$ depend on the potentials evaluated on the background solution. Note that [10] uses the DGSZ form of Horndeski's theory [5], so $\mathcal{G}_T$ and $\mathcal{F}_T$ are given in terms of DGSZ potentials. The DGSZ potentials for the *Fab-Four* are given in Appendix C of [14], so we can use this to extract the form of $\mathcal{G}_T$ and $\mathcal{F}_T$ for the cases we are interested in. We shall spare the reader the details, since they add little to this discussion.

Upon integrating out the lapse and the shift, the scalar perturbations yield the following effective action,

$$S_{scalar} = \int dt d^3x a^3 \left[\mathcal{G}_S \dot{\zeta}^2 - \frac{\mathcal{F}_S}{a^2} (\vec{\nabla} \zeta)^2 \right]. \tag{157}$$

Again, the coefficients $\mathcal{G}_S$ and $\mathcal{F}_S$ depend on the DGSZ potentials evaluated on the background solution.

Now, to avoid a ghost instability, we require

$$\mathcal{G}_T > 0, \qquad \mathcal{G}_S > 0, \tag{158}$$

and to avoid a gradient instability, we require

$$\mathcal{F}_T > 0, \qquad \mathcal{F}_S > 0. \tag{159}$$

We first consider the Matter I and Matter II solutions given by (133) and (135), which, as we have seen, are late time cosmological attractors for vanishing spatial curvature, even when the cosmological constant is non-zero. Plugging this solution into the appropriate formulae for $\mathcal{G}_T$, etc, we find that

$$\mathcal{G}_{T,S} \propto c_1 t^{\frac{2}{3}\hat{n}+2}, \qquad \mathcal{F}_{T,S} \propto c_1 t^{\frac{2}{3}\hat{n}+2}. \tag{160}$$

However, the crucial thing to know is the sign of each of these coefficients. These are plotted in figure 6. In each case the *un*shaded area correspond to regions of parameter space in which *all* coefficients are positive. We immediately see that it is not too difficult to guarantee the absence of ghost and gradient instabilities for both Matter I and Matter II.

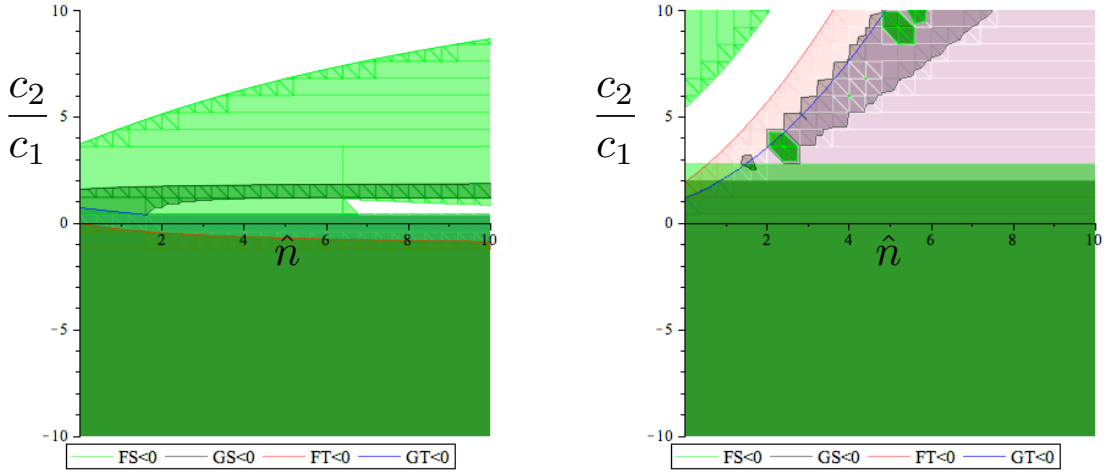

FIG. 6: Stable and unstable regions of parameter space for Matter I solution (left panel) and Matter II solution (right panel). In each the shaded regions have one or more ghost/gradient instability. The white, unshaded, regions have no such pathologies and are stable against cosmological perturbations.

The Matter III potentials do not give rise to such well behaved cosmological perturbations about the solution (153). Tensor perturbations are fine, with no ghost or gradient instability

$$\mathcal{G}_T \sim 28M^4t^2, \qquad \mathcal{F}_T \sim 104M^4t^2, \tag{161}$$

for some real mass scale M. In contrast, the scalar perturbations exhibit a gradient instability

$$\mathcal{G}_S \sim \frac{21}{2}M^4t^2, \qquad \mathcal{F}_S \sim -\frac{85}{6}M^4t^2. \tag{162}$$

For modes of wavelength λ this instability manifests itself on timescales $t_{instability} \sim \lambda/|c_s|$, where $|c_s| = \sqrt{\left|\frac{\mathcal{F}_S}{\mathcal{G}_S}\right|} \sim \mathcal{O}(1)$. This is far too quick, and rules out the Matter III solution as part of a viable cosmology.

VI. CONCLUSIONS

Obtaining a sensible cosmology in the presence of a large and changing contribution to the vacuum energy ρ_Λ is one of major challenges facing the self tuning scenario that we have developed in [2, 14]. A standard cosmological evolution arising out of General Relativity with large ρ_Λ would be totally unacceptable apart from perhaps in the early Universe where it would drive a period of accelerated expansion. There would be no way of exiting this period of inflation and obtaining a period of radiation and matter domination required for nucleosynthesis and structure formation. The goal of this paper is to demonstrate that for the *Fab-Four* , it is indeed possible to obtain a sensible cosmological history even in the presence of a large ρ_Λ contribution at all times. In other words, the self tuning of the cosmological constant can be accommodated in a sensible cosmological timeline.

To show this we have developed a dynamical systems approach in which fixed point solutions corresponding to inflationary, radiation and matter dominated solutions are made manifest. Two key approaches are developed. In the first, we explicitly include the ρ_Λ contribution and by demanding that all contributions in the Hamiltonian constraint remain independent of the Hubble parameter, we show that there exist a class of scaling solutions corresponding to the cosmologies we are looking for (recall there is no requirement here to actually include matter or radiation sources, the scalar field is doing the work for us). However, it turns out that this particular matter dominated solution (called "Matter III"), whilst perfectly acceptable at the background level, actually contains a gradient instability when perturbed, an instability that would grow on too fast a timescale to be compatible with observations. This has led us to consider a second complementary approach. Rather than obtain background solutions in the presence of ρ_Λ we set it to zero and look for consistent solutions that can also mimic matter domination ($H^2 \propto a^{-3}$). Our requirement that the Hamiltonian constraint be independent of the Hubble parameter is now lifted and this allows for more freedom introducing an extra parameter (we call n or equivalently, $\hat{n}$) in the background solutions. We find two new classes of matter-like solutions (called "Matter I" and "Matter") for arbitrary $\hat{n}$.

It would seem to go against the self-tuning spirit of the *Fab-Four* that the "Matter I" and "Matter II" solutions only correspond to fixed points for vanishing cosmological constant. However, we have shown that they can still represent an excellent approximation even when a large ρ_Λ is turned on, provided $\hat{n} > 0$. This is because the solution gets corrected by $\rho_\Lambda/a^{\hat{n}}$, a correction that decreases with time as the scale factor grows. Using analytic methods, we also showed that for vanishing spatial curvature, these solutions are cosmological attractors for $\hat{n} > 0$. Once spatial curvature is reintroduced alongside the cosmological constant, we are forced to use numerical simulations which reproduce the expected behaviour: a long period of matter-domination, before asymptoting to the self-tuning Milne Universe. For the record, the Lagrangians for the "Matter I" and "Matter II" cosmologies are given by

$$\begin{aligned}
\mathcal{L}_{\text{"Matter I"}} &= c_1\phi^{\hat{n}+4}G^{\mu\nu}\nabla_\mu\phi\nabla_\nu\phi + c_2\phi^{\hat{n}+6}P^{\mu\nu\alpha\beta}\nabla_\mu\phi\nabla_\alpha\phi\nabla_\nu\nabla_\beta\phi + \frac{2\hat{n}-3}{16(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6}\hat{\mathcal{G}},\\
\mathcal{L}_{\text{"Matter II"}} &= c_1\phi^{\hat{n}+4}G^{\mu\nu}\nabla_\mu\phi\nabla_\nu\phi + c_2\phi^{\hat{n}+3}R - \frac{(\hat{n}+3)(2\hat{n}+5)}{8(2\hat{n}+7)(\hat{n}+6)}c_1\phi^{\hat{n}+6}\hat{\mathcal{G}},
\end{aligned}$$

with the parameters $\hat{n} > 0$, c_1 and c_2 chosen so that they correspond to the perturbatively stable *un*shaded regions shown in figure 6. Indeed, perhaps the most exciting new feature of the corresponding solutions, is that they can be stable against cosmological perturbations for large regions of parameter space when spatial curvature is negelcted. This opens up the possibility of a sensible matter dominated period of evolution, hence of structure formation in the *Fab-Four* scenario. Furthermore, these solutions are behaving in such a way that the scalar screens the pressure component of the cosmological constant before the energy density. At least for homogeneous and isotropic backgrounds, this suggests that the cosmological constant is being forced to behave like cold dark matter. It is certainly tempting to ask whether such behaviour extends to inhomogeneous solutions, and recent results suggest that it may well be possible to have a *Fab-Four* scenario satisfying current solar system constraints [18].

There is much that remains to be done. We have not yet obtained a full cosmology, but the fact that we have a class of background polynomial potentials that we know can provide the various cosmological epochs we want to reproduce offers us some direction. Indeed we can speculate as to how we might sew together these interesting potentials to achieve the desired results. The point is that the scalar field is continually evolving,

so we could arrange for the potential to correspond to different fluid behaviours for different ranges of ϕ. For example, if we want radiation domination for $H^2 > H_{eq}^2$ and "Matter I" like behaviour for $H^2 < H_{eq}^2$, we might propose a Lagrangian of the form

$$\mathcal{L} = \frac{m^4}{H_{eq}^2}\phi^{\hat{n}}R + \mathcal{L}_{\text{"Matter I"}}\Big|_{c_1\sim\mathcal{O}(1),c_2\sim\mathcal{O}(m^{-2})}, \tag{163}$$

Plugging in the "Matter I' solution (133), we see that

$$\frac{m^4}{H_{eq}^2}\phi^{\hat{n}}R \sim m^4 a^{\hat{n}}\left(\frac{a_{eq}}{a}\right)^3, \qquad \mathcal{L}_{\text{"Matter I"}}\Big|_{c_1\sim\mathcal{O}(1),c_2\sim\mathcal{O}(m^{-2})} \sim m^4 a^{\hat{n}}, \tag{164}$$

where $a_{eq} = (m/H_{eq})^{2/3}$ is the value of the scale factor when $H = H_{eq}$. We see that the "Matter I" terms dominate for $a > a_{eq}$, as desired for mater domination. For $a < a_{eq}$ the $\phi^{\hat{n}}R$ term becomes important, and might be expected to dominate the dynamics, yielding an earlier period of radiation domination. The same may be done to evade the graceful exit problem due to the inflationary solutions being attractors.
